$C_0$–continuity of the Fröbenius–Perron Semigroup

Andrés Navas & Sergio Plaza *

Abstract

We consider the Fröbenius–Perron semigroup of linear operators associated to a semidynamical system defined in a topological space $X$ endowed with a finite or $\sigma$–finite regular measure. We prove that if there exists a faithful invariant measure for the semidynamical system, then the Fröbenius–Perron semigroup of linear operators is $C_0$–continuous in the space $L^1_\mu(X)$. We also give a geometrical condition which ensures $C_0$–continuity of the Fröbenius–Perron semigroup of linear operators in the space $L^p_\mu(X)$ for $1 \leq p < \infty$, as well as in the space $L^1_{\text{loc}}$.

1 Introduction

An important problem in the study of the dynamics of nonsingular transformations is to know if they admit an absolutely continuous invariant measure (acim). For interval maps, for example, we have a theorem of Lasota-Yorke [5], which roughly

Key words and phrases. Semigroups of Fröbenius–Perron operators, $C_0$–continuity, invariant measures, semidynamical systems

2000 Mathematics Subject Classification. 37A10, 47D03, 47D60.
states that if the map is smooth by parts \((C^r, \text{ with } r \geq 2)\) and expanding, then it admits an acim, and with some additional conditions it is exact with respect to this acim (see [5] for more details); extensions of this result have been obtained for the \(n\)-dimensional case (see [2]). When we deal with a continuous semidynamical or a dynamical system (i.e., with a semi-flow or a flow) the problem is more complicated.

A useful technical tool for study the problem of the existence of an acim is the Fröbenius–Perron operator (see [2], [4]). Let \(X\) be a topological space and let \(\mu\) be a regular measure defined on the Borel \(\sigma\)-algebra \(A\) of \(X\) (see below for definition), if \(\tau : X \to X\) is a nonsingular transformation then the Fröbenius–Perron operator associated to \(\tau\), denoted by \(P_\tau\) (in fact \(P_\tau\) depend also on \(\mu\), and some time we use the notation \(P_{\tau,\mu}\) in order to indicate such dependence on the measure), is a linear operator, naturally defined in the space \(L^1_\mu(X)\). The central point here is that an invariant density, that is, a non negative measurable function of unit norm and fixed for the Fröbenius–Perron operator corresponds to a density of an acim for the transformation \(\tau\) (see Section 2.4).

Let \(\tau_t : X \to X\) be a semidynamical system. Denote by \(P_t\) the Fröbenius–Perron operator associated to the transformation \(\tau_t\). The family \(\{P_t\}_{t \geq 0} = \{P_{t,\mu}\}_{t \geq 0}\) satisfies
\[
\begin{align*}
P_0 & = \text{Id}, \\
P_{t+s} & = P_t \circ P_s, \quad \text{for all } t, s \geq 0.
\end{align*}
\]

For a semigroup of continuous linear operators defined in the space \(L^1_\mu(X)\) a central problem is to know if the semigroup is \(C_0\)-continuous, that is, if the following holds:
\[
\lim_{t \to 0} P_t(f) = f, \quad \text{for all } f \in L^1_\mu(X). \tag{1}
\]

If this is the case, we may consider the infinitesimal generator of the semigroup which is defined by
\[
A(f) = \lim_{t \to 0} \frac{P_t(f) - f}{t}, \quad \tag{1'}
\]
for elements \( f \in L^1_\mu(X) \) for which the above limit exists (see [3], [6]). It is known
that a function \( f : X \to R \) satisfies \( P_t(f) = f \), for all \( t \geq 0 \), if and only if \( A \) is
defined for \( f \) and the differential equation \( A(f) = 0 \) is satisfied. In this way, the
problem of finding or proving the existence of an acim for the semidynamical system
is equivalent to the problem of find or prove the existence of a nontrivial zero for
the infinitesimal generator of the Fröbenius–Perron semigroup of linear operators
associated, provided that this semigroup is strongly continuous.

Let \( V \) be a smooth vector field defined in a smooth manifold, and let \( \{\tau_t\}_{t \in R} \) be
it flow. In this case, the Fröbenius–Perron operator, for \( f \) of class \( C^1 \) is given by the
equation \( A(f) = \nabla(fV) \) (where \( \nabla \) denote the divergence operator) . We recover
in this way a well known theorem of Liouville which states that a flow preserves the
canonical measure in the manifold if and only if the vector field has divergence equal
to zero. The operator \( A \) defined in equation (1’) can be viewed as a generalization of
the divergence operator for continuous semiflows for which the associated Fröbenius–
Perron semigroup of linear operators is \( C_0 \)–continuous.

In this paper we study general conditions that ensures this \( C_0 \)–continuity.

In section 2 we establish the notation and recall some basic results from semi-
group theory, and definition of the Fröbenius–Perron and some of its properties.

In Section 3 we consider the case in which we know a priori that there exists a
faithful acim for the system, that is, an acim with a positive density. In that case,
we prove the following result (theorem 2).

**Theorem** Let \( \{\tau_t\}_{t \geq 0} \) be a continuous semidynamical system. Suppose that \( \{\tau_t\}_{t \geq 0} \)
has a faithful acim. Then the associated Fröbenius–Perron semigroup of linear operators
\( \{P_{t,\mu}\}_{t \geq 0} \) is \( C_0 \)–continuous in the space \( L^1_\mu(X) \).

This theorem implies that the problem of find a faithful acim is equivalent to
the problem of find a zero for the infinitesimal generator.

Since the problem to deal with is exactly the problem of the existence of the
acim, we have to search an intrinsic property of the flow that ensures the strong
continuity of the semigroup. The condition is: there exist \( T > 0 \) such that

\[
\frac{\mu(\tau_t^{-1}(A))}{\mu(A)} \leq M \quad \text{for all } t \leq T \text{ and for all } A \in \mathcal{A}.
\] (2)

To understand condition (2) we may consider the case of a dynamical system. In that case each transformation \( \tau_t : X \to X \) has inverse, and the associated Fröbenius–Perron operator is given by

\[
P_t(f) = (f \circ \tau_t) \cdot J(\tau_t),
\] (3)

where \( J(\tau_t) \) is the density of the measure \( (\tau_t)_*(\mu) \) (where \( (\tau_t)_*\mu(B) = \mu(\tau_t^{-1}(B)) \) for \( B \) measurable), that is,

\[
\mu(\tau_t^{-1}(A)) = \int_A J(\tau_t) d\mu
\]

for more details see [4].

Thus if we have an upper bound and well behaviour for \( J(\tau_t) \) near zero, then we use the dominated convergence theorem to prove that condition (1) hold for continuous functions. The extension of the result for arbitrary integrable functions is obtained using the fact that the set of continuous functions is dense in the space of integrable functions.

For a semidynamical system, we do not have an explicit expression like (3) for the associated Fröbenius–Perron operator. However, a bound of \( J(\tau_t) \) can be interpreted as an estimative of type that appear in condition (2).

In Section 4 we prove that, under general hypotheses, condition (2) holds if and only if the Fröbenius–Perron semigroup of linear operators can be defined in the space \( L^p_{\mu}(X) \), and it is \( C_0 \)-continuous in that space (see theorems 3 and 4.)

In Section 5 we prove that condition (2) also ensures strong continuity in the space \( L^1_{\mu}(X) \) when \( (X, \mathcal{A}, \mu) \) is a probability space (theorem 5). The precise statement of the main result is the following (for the concepts involved, see Section 2).
Theorem Let $X$ be a topological space endowed with a regular probability measure $\mu$. Let $\{\tau_t\}_{t \geq 0}$ be a continuous proper semidynamical system defined on $X$. If the semidynamical system satisfies (2), then the associated Fröbenius–Perron semigroup of linear operators is $C_0$–continuous in $L^1_\mu(X)$.

Finally, in order to do this work more complete, in section 6 we deal with the $L^1_{\mu,\text{loc}}(X)$ case. The presentation is quite informal since there are some technical difficulties derived from the fact that $L^1_{\mu,\text{loc}}(X)$ is only a locally convex space and not a Banach space (we must add some hypotheses in this case in order to make the semigroup approach to the acim problem available).

2 Basic Results

In this section we give a survey of definitions, results and notations that are necessary for the rest of the paper.

2.1 Measure Theory

Let $X$ be a topological space and let $\mathcal{A}$ be its Borel $\sigma$–algebra. Let $\mu$ be a measure defined over $\mathcal{A}$. We say that $\mu$ is regular if for all $A \in \mathcal{A}$ we have

$$\mu(A) = \sup\{\mu(K) : K \subset A, \text{ K compact}\} = \inf\{\mu(C) : A \subset C, \ C \text{ open}\}.$$

We note that if $X$ is a metric space then a probability measure defined on the Borel $\sigma$–algebra is regular. In general, if a measure $\mu$ is regular then the set of continuous functions with compact support is dense in the space $L^p_\mu(X)$, for all $1 \leq p < \infty$.

2.2 Semidynamical Systems

Let $X$ be a topological space. A family $\{\tau_t\}_{t \geq 0}$ of continuous transformations $\tau_t : X \to X$ is a semidynamical system if the following conditions are satisfied:
i) \( \tau_0 = Id \),

ii) \( \tau_t \circ \tau_s = \tau_{t+s} \) for all \( t, s \geq 0 \), and

iii) the map \([0, \infty] \times X \to X\) given by \((t, x) \to \tau_t(x)\) is continuous.

If each transformation \( \tau_t \) has a continuous inverse \( \tau_{-t} \) then the family \( \{\tau_t\}_{t \in \mathbb{R}} \) is a continuous flow. However, for general semidynamical systems, the maps \( \tau_t \) may no necessarily have inverse.

We say that a semidynamical system \( \{\tau_t\}_{t \in \mathbb{R}} \) is proper if, for each compact set \( K \subset X \) and for each \( t > 0 \) the set \( \bigcup_{s \leq t} \tau_s^{-1}(K) \) is compact.

### 2.3 Semigroups in Banach Spaces

Let \( L \) be a Banach space with respect to a norm \( \|\cdot\|\). A family \( \{T_t\}_{t \geq 0} \) of continuous linear operators \( T_t : L \to L \ (t \geq 0) \) is called a semigroup of linear operators if the following conditions are satisfied:

\[
\begin{align*}
T_0 &= Id, \\
T_{t+s} &= T_t \circ T_s, \text{ for all } t, s \geq 0.
\end{align*}
\]

For more details see [6] or [3]. We say that a semigroup \( \{T_t\}_{t \geq 0} \) of linear operators is \( C_0 \)-continuous, if

\[
\lim_{t \to 0} \|T_t(f) - f\| = 0 \quad \text{for all } f \in L.
\]

When a semigroup \( \{T_t\}_{t \geq 0} \) is \( C_0 \)-continuous, there exist constants \( M \geq 1 \) and \( w \geq 0 \) such that, for all \( f \in L \) we have

\[
\|T_t(f)\| \leq Me^{wt} \|f\|.
\]

If \( \{T_t\}_{t \geq 0} \) is a semigroup defined on \( L \), then the adjoint family \( \{T^*_t\}_{t \geq 0} \) is a semigroup defined on the dual space \( L^* \). By a duality theorem we have that if \( \{T_t\}_{t \geq 0} \) is \( C_0 \)-continuous and \( L \) is reflexive, then \( \{T^*_t\}_{t \geq 0} \) is \( C_0 \)-continuous in \( L^* \) (see [6], Corollary 10.6, page 41).
2.4 Fröbenius–Perron Operator

Let \((X, \mu, \mathcal{A})\) be a measure space. We say that a transformation \(\tau : X \to X\) is non singular if for all \(A \in \mathcal{A}\) such that \(\mu(A) = 0\), we have \(\mu(\tau^{-1}(A)) = 0\). If a transformation \(\tau : X \to X\) is nonsingular then associated to it there exists a linear operator \(P_\tau = P_{\tau, \mu} : L^1_\mu(X) \to L^1_\mu(X)\), called Fröbenius–Perron operator which is characterized by the relation:

\[
\int_A P_\tau(f) \, d\mu = \int_{\tau^{-1}(A)} f \, d\mu \tag{4}
\]

for all \(f \in L^1_\mu(X)\) and all \(A \in \mathcal{A}\).

It is well known (see [1], [4]) that a probability measure \(\mu\) on \(X\) is \(\tau\)-invariant (that is, \(\mu(\tau^{-1}(A)) = \mu(A)\) for all \(A \in \mathcal{A}\)) if and only if \(P_\tau(1) = 1\) (this is also true for \(\sigma\)-finite measure spaces, but in that case there is a problem with the space where the Fröbenius–Perron operator is defined, as we shall see). In general, \(\tau\) preserves a measure \(\nu = fd\mu\), with \(f \in L^1_\mu(X)\), if and only if \(P_\tau(f) = f\). It is also well known that the Fröbenius–Perron operator is a linear contraction in the \(L^1_\mu(X)\) norm, that is, \(||P_\tau||_{L^1_\mu} \leq 1\) (see [4], [2]). Moreover, for \(f \in L^1_\mu(X)\) and a.e. \(x \in X\), we have \(|P(f)(x)| \leq P(|f|)(x)\). On the other hand, if we change the measure \(\mu\) by an absolutely continuous one given by \(d\nu = gd\mu\), then the change in Fröbenius–Perron operator is given by

\[
P_{\tau, \nu} = \frac{P_{\tau, \mu}(f \cdot g)}{g}. \tag{5}
\]

Another important property of the Fröbenius–Perron operator is given by the equality

\[
\int_X P_\tau(f) \cdot g \, d\mu = \int_X f \cdot (g \circ \tau) \, d\mu, \tag{6}
\]

valid for all \(f \in L^1_\mu(X)\) and all \(g \in L^\infty_\mu(X)\). Equation (6) permit us define a linear operator \(K_\tau : L^\infty_\mu(X) \to L^\infty_\mu(X)\) given by \(K_\tau(g) = g \circ \tau\). The operator \(K_\tau\) is well defined if \(\tau\) is a nonsingular transformations. This operator is called the Koopman operator. For more details about these concepts see [1] or [4].
If we have a semidynamical system \( \{\tau_t\}_{t \geq 0} \) such that each transformation \( \tau_t \) is nonsingular, then we denotes the family of Fröbenius–Perron operators associated by \( P_t = P_{\tau_t} \), this is a semigroup of continuous linear operators in the space \( L^1_\mu(X) \) (see [4]). We will also use the notation \( K_t \) for the Koopman operator \( K_{\tau_t} \).

We note that Fröbenius–Perron operator may also be defined and is bounded in other spaces of functions if the transformation \( \tau \) has a good behaviour, for example, \( L^p_\mu(X) \) spaces or \( BV(X) \), the space of functions of bounded variation. For example, in Section 4 we consider this operator in \( L^p_\mu(X) \) spaces, and we prove that the geometrical condition (3) ensures continuity of each operator \( P_t \) (and also the \( C_0 \)–continuity of the semigroup \( \{P_t\}_{t \geq 0} \) in the space \( L^p_\mu(X) \)). We note that if \( P_t \) is continuous in \( L^p_\mu(X) \), then the duality equation (6) is valid for all \( f \in L^p_\mu(X) \) and for all \( g \in L^q_\mu(X) \), with \( \frac{1}{p} + \frac{1}{q} = 1 \), that is, \( K_t \) is the adjoint operator of \( P_t \).

2.5 Conditional Expectation and Fröbenius–Perron Operator

Let \((X, \mathcal{A}, \mu)\) be a probability space. Suppose \( \tau : X \to X \) preserves \( \mu \), then we have another way of introducing the Fröbenius–Perron operator associated to \( \tau \). This is given for \( f \in L^1_\mu(X) \) by the equality

\[
P_\tau(f) \circ \tau = E(f, \tau^{-1}(\mathcal{A})),
\]

where the expression on the right hand denotes the conditional expectation of \( f \) with respect to the \( \sigma \)-algebra \( \tau^{-1}(\mathcal{A}) \). In Section 3 we use this approach and the following result of convergence that arises in martingale theory (see [1], page 81).

**Theorem 1** Let \( \{\mathcal{A}_n\}_{n \in \mathbb{N}} \) be a collection of \( \sigma \)-algebras such that \( \mathcal{A}_n \subset \mathcal{A}_{n+1} \), for all \( n \). Then \( E(f, \mathcal{A}_n) \) converges to \( E(f, \mathcal{A}_\infty) \), in the \( L^1 \) sense, where \( \mathcal{A}_\infty \) denotes the \( \sigma \)-algebra generated by all the \( \mathcal{A}_n \).
3 Strong continuity with an absolutely continuous invariant measure

Let $X$ be a topological space and let $\mu$ be a regular probability measure defined on the Borel $\sigma$–algebra on $X$. In this section we consider a nonsingular semi–dynamical system $\{\tau_t\}_{t \geq 0}$ defined over $X$. We prove that if there exists a faithful acim (an acim of positive density), then the associated Fröbenius–Perron semigroup is $C_0$–continuous in $L^1_\mu(X)$. We first prove two lemmas.

**Lemma 1** Suppose that $\{\tau_t\}_{t \geq 0}$ has an acim $\nu$ such that $d\nu = gd\mu$, with $g > 0$ (a.e.). Then, for each $f \in L^1_\nu(X)$, we have, in the $L^1_\nu(X)$ sense, that

$$\lim_{t \to 0} (P_t,\nu(f) \circ \tau_t) = f.$$

**Proof.** The sequence of $\sigma$–algebras $\{A_t\}_{t \geq 0}$, where $A_t = \tau_t^{-1}(A)$ for all $t \geq 0$, is increasing as $t$ goes to zero. By the martingale convergence theorem, we have, for $f$ in $L^1_\nu(X)$,

$$\lim_{t \to 0} (P_t,\nu(f) \circ \tau_t) = E(f, A_\infty),$$

where $A_\infty$ is the $\sigma$–algebra generated by all the $\sigma$–algebra $A_t$. Thus, we must prove that $A_\infty$ is equal to $A$. For this, let $A$ be an open set. By continuity of the semidynamical system $\{\tau_t\}_{t \geq 0}$, the function $|X_A \circ \tau_t - X_A|$ converges pointwise to zero as $t$ goes to zero and by the dominated convergence theorem, we have

$$\nu(\tau_t^{-1}(A) \Delta (A)) = \int_X |X_A \circ \tau_t - X_A| d\nu$$

converges to zero as $t$ goes to zero. Thus, for each $n \in N$, we may consider a sequence $t_n > 0$ such that $\nu(\tau_t^{-1}(A) \Delta (A)) < 1/2^n$, from this it is easy to see that $\nu(\bigcup_{n \geq m} \tau_t^{-1}(A) \Delta (A)) < 1/2^{m-1}$. Hence

$$\nu((\cap_{m=1}^{\infty} \bigcup_{n \geq m} \tau_t^{-1}(A)) \Delta (A)) \leq \nu(\cap_{m=1}^{\infty} (\bigcup_{n \geq m} \tau_t^{-1}(A) \Delta (A))) = 0.$$
This implies that $A \in \mathcal{A}_\infty$, and since $A$ is an arbitrary open set, this implies that $\mathcal{A}_\infty$ is equal to $\mathcal{A}$, which completes the proof of Lemma 1.

**Lemma 2** Suppose that \{\tau_t\}_{t \geq 0} has a faithful acim $\nu$ given by $d\nu = gd\mu$, with $g \in L^1_\mu(X)$ and $g > 0$ (a.e.). Then, for each $f \in L^1_\nu(X)$, we have, in the $L^1_\nu(X)$ sense, that

$$\lim_{t \to 0} P_{t,\nu}(f) = f.$$

**Proof.** Let $\varepsilon$ be an arbitrary positive number. We take a sequence \{f_n\}_{n \in N} of bounded continuous functions that converges to a function $f \in L^1_\nu(X)$ and choose $n_0 \in N$ such that $\|f_n - f\| \leq \varepsilon/4$. By the invariance of $\nu$ and since the operator $P_{t,\nu}$ is a linear contraction, we have

$$\|P_{t,\nu}(f_n) - f_n\|_{L^1_\nu} \leq \frac{\varepsilon}{2} + \|P_{t,\nu}(f_n) \circ \tau_t - f_n \circ \tau_t\|_{L^1_\nu}.$$

For small $t$, by Lemma 1 we have $\|P_{t,\nu}(f_n) \circ \tau_t - f_n\|_{L^1_\nu} \leq \varepsilon/4$. Now by continuity of the semidynamical system and by the dominated convergence theorem, we have

$$\lim_{t \to 0} \|P_{t,\nu}(f_n) - f_n\|_{L^1_\nu} = 0.$$ 

This implies, for $t$ small, that $\|P_{t,\nu}(f) - f\|_{L^1_\nu} \leq \varepsilon$, which completes the proof of Lemma 2.

**Theorem 2** Suppose that the semidynamical system \{\tau_t\}_{t \geq 0} has a faithful acim. Then the semigroup \{P_{t,\mu}\}_{t \geq 0} is $C_0$–continuous in $L^1_\mu(X)$.

**Proof.** Let $\nu$ the faithful acim given by $d\nu = gd\mu$, with $g \in L^1_\mu(X)$ and $g > 0$ (a.e.). Let $f \in L^1_\mu(X)$. Then $\frac{f}{g} \in L^1_\nu(X)$, and we have, by equality (5), that

$$\|P_{t,\mu}(f) - f\|_{L^1_\mu} = \int_X \left| P_{t,\mu}(f) - f \right| d\mu$$

$$= \int_X \left| g P_{t,\nu} \left( \frac{f}{g} \right) - f \right| d\mu$$

$$= \int_X \left| \frac{f}{g} - \frac{f}{g} \right| d\nu.$$
By Lemma 2 the last quantity converges to zero as \( t \) goes to zero, which proves the theorem.

4 Strong Continuity in \( L^p \)

In this section we consider a semidynamical system defined over a topological space \( X \) provided of a regular measure \( \mu \) defined on its Borel \( \sigma \)-algebra, and prove that condition (2) is equivalent to strong continuity of the associated Fröbenius–Perron semigroup defined over the space \( L^p_\mu(X) \).

We say that a semidynamical system is strongly nonsingular if satisfies condition (2). It is easy to see that the following conditions for being strongly nonsingular are equivalent:

i) For each \( t > 0 \), there exists \( M_t \) such that

\[
\mu(\tau^{-1}_s(A)) \leq M_t \mu(A)
\]  

(7)

for all \( s \leq t \) and all \( A \in \mathcal{A} \).

ii) There exist \( T > 0 \) and \( M = M_T > 0 \) such that

\[
\mu(\tau^{-1}_s(A)) \leq M_T \mu(A)
\]  

(8)

for all \( A \in \mathcal{A} \) and all \( s \leq T \).

In fact, condition (7) implies trivially (8), and if condition (8) is assumed, then condition (7) holds by putting \( M_t = M_t^{T+1} \).

Finally, it is easy to see that every strongly nonsingular semidynamical system is nonsingular.

**Theorem 3** Let \( \{\tau_t\}_{t \geq 0} \) be a nonsingular semidynamical system such that its associated semigroup of Fröbenius–Perron operators \( \{P_t\}_{t \geq 0} \) is a \( C_0 \)-continuous semi-
group of bounded linear operators in the space \( L^p_\mu(X) \) for some \( 1 < p \leq \infty \). Then \( \{\tau_t\}_{t \geq 0} \) is strongly nonsingular.

**Proof.** By the hypothesis, the semigroup of linear operators \( \{P_t\}_{t \geq 0} \) is a \( C_0 \)-semigroup over a reflexive space. Thus, the semigroup of Koopman operators \( \{K_t\}_{t \geq 0} \) is a \( C_0 \)-semigroup in the space \( L^q_\mu(X) \), where \( q = \frac{p}{p-1} \) is the conjugate of \( p \) (see [6], Corollary 10.6, page 41). Therefore, there exist constants \( M \geq 1 \) and \( w > 0 \) such that, for all \( f \in L^q_\mu(X) \) we have that \( \|K_t(f)\|_{L^q_\mu} \leq M e^{wt} \|f\|_{L^q_\mu} \). Now, if \( \mu(A) \) is finite then \( \mathcal{X}_A \subseteq L^q_\mu(X) \) and \( \|K_t(\mathcal{X}_A)\|_{L^q_\mu} \leq M e^{wt} \|\mathcal{X}_A\|_{L^q_\mu} \). Thus, \( \|\mathcal{X}_{\tau_t^{-1}(A)}\|_{L^q_\mu} \leq M e^{wt} (\mu(A))^{\frac{1}{q}} \) and from this it follows that \( \mu(\tau_t^{-1}(A)) \leq (M e^{wt})^q \mu(A) \), which proves our theorem.

If a measure \( \mu \) is regular and the semidynamical system \( \{\tau_t\}_{t \geq 0} \) is proper, then we have the converse of the above result.

**Theorem 4** Let \( \mu \) be a regular measure defined on \( X \). If \( \{\tau_t\}_{t \geq 0} \) is a proper and strongly nonsingular semidynamical system. Then, for all \( 1 < p < \infty \), the associated Fröbenius–Perron semigroup \( \{P_t\}_{t \geq 0} \) is a \( C_0 \)-semigroup of linear bounded operators in the space \( L^p_\mu(X) \).

The idea for the proof of theorem 4, is prove that condition (7) ensures strong continuity for the dual semigroup \( \{K_t\}_{t \geq 0} \) in the dual space \( L^q_\mu(X) \). For this we first prove two lemmas.

**Lemma 3** Under the hypotheses of theorem 4, we have \( \|K_s(f)\|_{L^q_\mu} \leq M_t^{1/q} \|f\|_{L^q_\mu} \) for all \( f \in L^q_\mu(X) \) and all \( s \leq t \).

**Proof.** Let \( f \in L^q_\mu(X) \) be a simple function given by \( f = \sum_{i=1}^n \lambda_i \mathcal{X}_{A_i} \), with \( A_i \cap A_j = \emptyset \), for \( i \neq j \), then we have \( \|f\|_{L^q_\mu} = (\sum_{i=1}^n |\lambda_i|^q \mu(A_i))^{1/q} \) and \( \|K_t(f)\|_{L^q_\mu} = (\sum_{i=1}^n |\lambda_i|^q \mu(\tau_t^{-1}(A_i)))^{1/q} \). On the other hand, by condition (7) we have, for \( s \leq t \), that \( (\sum_{i=1}^n |\lambda_i|^q \mu(\tau_t^{-1}(A_i)))^{1/q} \leq (\sum_{i=1}^n |\lambda_i|^q M_t \mu(A_i))^{1/q} \), and this implies that \( \|K_s(f)\|_{L^q_\mu} \leq M_t^{1/q} \|f\|_{L^q_\mu} \). Finally, since the set of simple functions is dense in the space \( L^q_\mu(X) \), the lemma follows.
Lemma 4 If the hypotheses of theorem 3 are satisfied then the Koopman semigroup of operators \( \{K_t\}_{t \geq 0} \) is a \( C_0 \)-continuous semigroup of linear bounded operators in the space \( L^q_\mu(X) \).

Proof. Let \( f \in L^q_\mu(X) \) and let \( \varepsilon > 0 \). We take a sequence \( \{f_n\}_{n \in \mathbb{N}} \) of continuous functions with compact support, say \( K \), such that \( \lim_{n \to \infty} \|f_n - f\|_{L^q_\mu} = 0 \) and we choose \( n_0 \in \mathbb{N} \) such that

\[
\|f - f_{n_0}\|_{L^q_\mu} \leq \frac{\varepsilon}{2(M_1^q + 1)},
\]

where \( M = M_T \) is fixed. By continuity of the Koopman semigroup, the function \( K_s(f_{n_0}) - f_{n_0} \) converges pointwise to zero as \( s \) goes to zero. If \( K \) is the support of \( f_{n_0} \) then, since the semidynamical system is proper, the set \( \tilde{K} = \bigcup_{s \leq t} T_s^{-1}(K) \) is compact. Now, it is clear that \( \text{supp}(K_s(f_{n_0}) - f_{n_0}) \subset \tilde{K} \) for \( s \leq t \), and by the dominated convergence theorem we have \( \lim_{s \to 0} \|K_s(f_{n_0}) - f_{n_0}\|_{L^q_\mu} = 0 \). Thus, we may take \( t_0 > 0 \) such that, for all \( s \leq t_0 \), we have

\[
\|K_s(f_{n_0}) - f_{n_0}\|_{L^q_\mu} \leq \frac{\varepsilon}{2}.
\]

Using the above inequalities, we have, for \( s \leq \min\{T, t_0\} \), that

\[
\|K_s(f) - f\|_{L^q_\mu} \leq \|K_s(f) - K_s(f_{n_0})\|_{L^q_\mu} + \|K_s(f_{n_0}) - f_{n_0}\|_{L^q_\mu} + \|f_{n_0} - f\|_{L^q_\mu} \leq (M_1^q + 1)\frac{\varepsilon}{2(M_1^q + 1)} + \frac{\varepsilon}{2} = \varepsilon
\]

which proves the lemma.

Proof of theorem 4. It follows direct by the duality theorem (see sections 2.3 and 2.4).

5 Strong continuity in \( L^1 \)

One of the most important applications of Fröbenius–Perron operator arise in probability spaces by considering its action over the space \( L^1_\mu(X) \). For that spaces we have the following result.
Theorem 5 Let $X$ be a topological space endowed with a regular probability measure $\mu$ and let $\{\tau_t\}_{t \geq 0}$ be a proper semidynamical system. If the semidynamical system is strongly nonsingular, then the associated Fröbenius–Perron semigroup of operators $\{P_t\}_{t \geq 0}$ is $C_0$–continuous in the space $L^1_\mu(X)$.

Proof. Let $f \in L^1_\mu(X)$ and $\varepsilon > 0$. We fix $p > 0$ and consider a sequence $\{f_n\}_{n \in \mathbb{N}}$ in $L^p_\mu(X)$ such that $\lim_{n \to \infty} \|f_n - f\|_{L^1_\mu} = 0$. Since $\mu(X) = 1$ we have

$$\|P_t(f) - f\|_{L^1_\mu} \leq \|P_t(f) - P_t(f_n)\|_{L^1_\mu} + \|P_t(f_n) - f_n\|_{L^1_\mu} + \|f_n - f\|_{L^1_\mu},$$

$$\leq 2\|f_n - f\|_{L^1_\mu} + \|P_t(f_n) - f_n\|_{L^p_\mu},$$

$$\leq 2\|f_n - f\|_{L^1_\mu} + \|P_t(f_n) - f_n\|_{L^p_\mu}.$$

We choose $n_0$ such that $\|f - f_{n_0}\|_{L^1_\mu} \leq \varepsilon/3$. By theorem 3 (see also remark 1), there exists $t_\varepsilon > 0$ such that $\|P_t(f_{n_0}) - f_{n_0}\|_{L^p_\mu} \leq \varepsilon/3$ for all $t \leq t_\varepsilon$. Therefore, for $t \leq t_\varepsilon$ we have $\|P_t(f) - f\|_{L^1_\mu} \leq \varepsilon$. Since $f$ and $\varepsilon$ are arbitrary, this finishes the proof.

The previous theorem is useful for compact metric spaces of finite measure, in that case $\{\tau_t\}_{t \geq 0}$ is proper. For noncompact or unbounded metric spaces with non–finite measure we assume that the system is strongly continuous over bounded sets, that is, we assume that for each ball

$$B = B(x_0, r) = \{x \in X : d(x, x_0) < r\}$$

there exists a constant $M = M(x, r)$ and $T = T(x, r)$ such that

$$\mu(\tau^{-1}_t(A) \cap B) \leq M \mu(A \cap B)$$

for all $t \leq T$ and $A \in \mathcal{A}$. Now we have the following theorem.

Theorem 6 Under the hypotheses of theorem 5, suppose also that the above condition (9) is true and the measure is finite over bounded sets. Then the Fröbenius–Perron semigroup is $C_0$–continuous in $L^1_\mu(X)$.
The proof of theorem 6 is based in a reduction of it to theorem 5 in each ball $B = B(x, r)$. For that, we define a new measure $\tilde{\mu}$ in $X$ by putting

$$\tilde{\mu}(A) = \mu(A \cap B).$$

This new measure is finite, and the semidynamical system $\{\tau_t\}_{t \geq 0}$ is strongly nonsingular with respect to $\tilde{\mu}$. By theorem 4, we have, for each $f \in L^1_{\tilde{\mu}}(X)$, that

$$\lim_{t \to 0} \tilde{P}_t(f) = f$$

in the $L^1_{\tilde{\mu}}$ sense, where $\tilde{P}_t = P_{t,\tilde{\mu}}$. Using this we prove the following.

**Lemma 5** Let $f \in L^1_{\text{loc}}(X, \mu)$ be a function of compact support $K$. Then

$$\lim_{t \to 0} \int_K |P_t(f) - f| d\mu = 0.$$

**Proof.** We take a ball $B = B(x, r)$ containing $K$ and we have

$$\int_K |P_t(f) - f| d\mu \leq \int_B |P_t(f) - f| d\mu \leq \int_B |P_t(f) - \tilde{P}_t(f)| d\mu + \int_B |\tilde{P}_t(f) - f| d\tilde{\mu}.$$

By (10), we have to prove that

$$\lim_{t \to 0} \int_B |\tilde{P}_t(f) - P_t(f)| d\mu = 0.$$

Let $k$ be a positive integer and let $C_{k,t}$ be the set

$$C_{k,t} = \left\{ x \in B : |P_t(f)(x) - \tilde{P}_t(f)(x)| \geq \frac{1}{k} \right\}.$$

We claim that $\mu(C_{k,t})$ converges to zero when $t$ goes to zero, for all $k$. To prove the claim we consider the sets

$$C^1_{k,t} = \left\{ x \in B : P_t(f)(x) - \tilde{P}_t(f)(x) \geq \frac{1}{k} \right\},$$
and
\[ C_{k,t}^2 = \left\{ x \in B : P_t(f)(x) - \tilde{P}_t(f)(x) \leq \frac{-1}{k} \right\}. \]

By (5) we have
\[ \int_{C_{k,t}^1} P_t(f) d\mu - \int_{C_{k,t}^1} \tilde{P}_t(f) d\mu = \int_{\tau^{-1}(C_{k,t}^1)} f d\mu - \int_{\tau^{-1}(C_{k,t}^1)} f d\tilde{\mu}, \]
and from this we have
\[ \frac{\mu(C_{k,t}^1)}{k} \leq \int_{\tau^{-1}(C_{k,t}^1) - B} f d\mu. \]

As in the proof of lemma 1, and using the fact that the system is proper, it is not
difficult to see that \( \mu(\tau^{-1}(B) - B) \) converges to zero when \( t \) goes to zero, which
implies that \( \mu(C_{k,t}^1) \) converges to zero. By the same way, \( \mu(C_{k,t}^2) \) converges to zero
with \( t \), and this proves our claim.

To finish the proof of the lemma 5, let \( \varepsilon > 0 \). We choose \( k \geq \frac{2\mu(B)}{\varepsilon} \) and we have
\[ \int_B |P_t(f) - \tilde{P}_t(f)| d\mu = \int_{C_{k,t}} |P_t(f) - \tilde{P}_t(f)| d\mu + \int_{B - C_{k,t}} |P_t(f) - \tilde{P}_t(f)| d\mu \]
\[ \int_B |P_t(f) - \tilde{P}_t(f)| d\mu \leq \frac{\varepsilon}{2} + \int_{C_{k,t}} |P_t(f) - \tilde{P}_t(f)| d\mu. \]

Finally we have
\[ \int_{C_{k,t}} |P_t(f) - \tilde{P}_t(f)| d\mu \leq \int_{C_{k,t}} (P_t(|f|) + \tilde{P}_t(|f|)) d\mu = \int_{\tau^{-1}(C_{k,t})} |f| d\mu + \int_{\tau^{-1}(C_{k,t})} |f| d\tilde{\mu}. \]
Since \( \tilde{\mu}(\tau^{-1}(C_{k,t})) \leq \tilde{M}\mu(C_{k,t}) \), and \( \mu(\tau(C_{k,t}^{-1})) \leq M\mu(C_{k,t}) + \mu(\tau^{-1}(B) - B) \), these
measures converge to zero (by the claim), and then the last two integrals have values
less than \( \varepsilon/4 \) for \( t \) small. This implies that
\[ \int_B |P_t(f) - \tilde{P}_t(f)| d\mu \leq \varepsilon \]
for \( t \) small, which finishes the proof.
Proof of theorem 6. Let $f \in L^1_{\mu}(X)$ and $\varepsilon > 0$ arbitrary. We take a sequence $\{f_n\}_{n \in \mathbb{N}}$ converging to $f$ and such that each $f_n$ has compact support. Then we have, as in the proof of Theorem 4, that

$$\int_X |P_t(f) - f|d\mu \leq 2\|f - f_n\|_{L^1} + \int_X |P_t(f_n) - f_n|d\mu.$$  

If we take $n_0 \in \mathbb{N}$ such that $\|f - f_{n_0}\| \leq \varepsilon/4$ then we have

$$\int_X |P_t(f) - f|d\mu \leq \frac{\varepsilon}{2} + \int_X |P_t(f_{n_0}) - f_{n_0}|d\mu.$$  

If $K$ is a compact set containing $\text{supp}(f_{n_0})$ then

$$\int_X |P_t(f) - f|d\mu \leq \frac{\varepsilon}{2} + \int_K |P_t(f_{n_0}) - f_{n_0}|d\mu + \int_{X-K} |P_t(f_{n_0})|d\mu.$$  

By lemma 5 we have, for $t$ small enough,

$$\int_K |P_t(f_{n_0}) - f_{n_0}|d\mu \leq \frac{\varepsilon}{4}.$$  

Also,

$$\int_{X-K} |P_t(f_{n_0})|d\mu \leq \int_{X-K} P_t(|f_{n_0}|)d\mu = \int_{\tau_t^{-1}(X-K)} f_{n_0}d\mu.$$  

Since $\int_{X-K} |f_{n_0}|d\mu = 0$ and $\mu\{\tau_t^{-1}(X-K) - (X-K)\}$ converges to zero, we have, for $t$ small,

$$\int_{X-K} |P_t(f_{n_0})|d\mu \leq \frac{\varepsilon}{4}.$$  

This implies that for small $t$ we have

$$\int_X |P_t(f) - f|d\mu \leq \varepsilon,$$

which finishes the proof.

6 Strong continuity in $L^1_{\text{loc}}$

Since $L^1_{\text{loc}}(X)$ is not a Banach space, the aproach of section 2.3 is not available here. However, there is a more general setting of semigroup theory for locally convex
spaces (see [7]). In this case, the hypothesis for the family \( \{T_t\}_{t \geq 0} \) of continuous linear operators \( T_t : L \to L \) are the following:

i) \( T_0 = Id \),

ii) \( T_t \circ T_s = T_{t+s} \) for all \( t, s \geq 0 \),

iii) \( \lim_{t \to t_0} T_t(f) = T_{t_0}(f) \) for all \( t_0 \geq 0 \) and \( f \in L \), and

iv) \( \{T_t\}_{t \geq 0} \) is an equicontinuous family, i.e., for any continuous seminorm \( p \) on \( L \) there exist a continuous seminorm \( q \) such that \( p(T_t(f)) \leq q(f) \) for all \( t \geq 0 \) and \( f \in L \).

If these conditions are satisfied, then the equality \( A(f) = 0 \) is equivalent to \( T_t(f) = f \) for all \( t \geq 0 \).

We consider the case where \( L = L^1_{\mu,loc}(X) \) and \( \{T_t\}_{t \geq 0} \) is the Fröbenius–Perron semigroup of linear operators associated to a semidynamical system \( \{\tau_t\}_{t \geq 0} \). Since conditions i) and ii) holds trivially, we consider conditions iii) and iv). For this we assume condition (9) and that the semidynamical system is strongly proper, i.e., for all compact set \( K \) the set \( \tilde{K} = \bigcup_{t \geq 0} \tau_{-t}^{-1}(K) \) is a compact set. This hypothesis is restrictive, but it permits to continue with our approach. In fact, condition iv) follows from it since for all \( f \geq 0 \) and all \( t \geq 0 \) we have

\[
\int_K P_t(f) d\mu = \int_{\tau_t^{-1}(K)} f d\mu \leq \int_{\tilde{K}} f d\mu.
\]

Finally, using the method of the proof of theorem 6, it is possible to prove that condition iii) also holds. Then, we have extended theorem 6 to \( L^1_{\mu,loc}(X) \) for a large class of systems defined over \( X \).
